1. DATA SETS

We received several data sets for the Network Analysis component. From the document reports stored in the original Lotus Notes database, Eugene Gavrilov created an SQL database for use by the entire project. From the first load of this database, the relation between people names and documents was deemed of interest. We refer to this as the **PEOPLE_DOCUMENTS1** dataset. Another relation between cities and documents was also studied: **CITIES_DOCUMENTS1**.

Later, when new documents and additional relations were added to the Lotus Notes database, Eugene Gavrilov updated the SQL database. From this novel database we again extracted the relation between people names and documents: **PEOPLE_DOCUMENTS2**. We furthermore extracted four additional relations of interest:

1. **EVENTS_GROUPS**: A Relation between terrorist events and terrorist organizations.
2. **EVENTS_PEOPLE**: A Relation between terrorist events and people names.
3. **GROUPS_PEOPLE**: A Relation between terrorist organizations and people names.
4. **PEOPLE_RELATEDPEOPLE**: A Relation between people names and other people names found in the related people field of the database.

2. PROXIMITY RELATIONS

2.1 Mathematical Background

2.1.1 Crisp Relations

“A crisp relation represents the presence or absence of association, interaction or interconnectedness between the elements of two or more sets.” ((Klir & Yuan 1995) page 119). In other words, a relation R between sets X_1, X_2, \dots, X_n is a subset of the Cartesian product of these sets: $R(X_1, X_2, \dots, X_n) \subseteq X_1 \times X_2 \times \dots \times X_n$. Thus, since a relation is itself a set, the traditional logical operations between sets can be used to modify relations. The elements of relations are n -tuples of the universal set $\mathbf{X} = X_1 \times X_2 \times \dots \times X_n$; $\mathbf{x} = (x_1, x_2, \dots, x_n)$. Relations can also be defined by a characteristic function which assigns a value of 1 to every element \mathbf{x} of \mathbf{X} belonging to the relation and a 0 to those elements not belonging to it:

$$R(x_1, x_2, \dots, x_n) = \begin{cases} 1 & \text{iff } (x_1, x_2, \dots, x_n) \in R \\ 0 & \text{otherwise} \end{cases}$$

The membership of \mathbf{x} in R signifies that the elements of \mathbf{x} are related or associated to one another ((Klir & Yuan 1995) page 119). Relations between two, three, four, and five sets are referred to as

binary, *ternary*, *quaternary*, and *quinary* respectively. A relation between n sets is generally referred to as a n -ary relation.

2.1.2 Fuzzy Relations

Naturally crisp relations can be generalized to fuzzy relations by allowing a degree of association between the elements of tuples \mathbf{x} . Thus, a fuzzy relation is a fuzzy set defined on \mathbf{X} .

$$R(\mathbf{x}) \in [0, 1], \quad \forall \mathbf{x} \in \mathbf{X}$$

The value of R represents the degree of association or strength of the relation between the elements of \mathbf{x} .

2.1.3 Binary Relations and Graphs

Binary relations are especially important because they are a generalization of functions, in that binary relations between sets X and Y may associate to each element of X two or more elements of Y , whereas functions can only assign one and only one element of Y to each element of X . Binary fuzzy relations, $R(X, Y)$, can be easily represented by matrices of dimension $n \times m$ where n and m are the number of elements of X and Y respectively.

Binary relations can also be defined on a single set: $R(X, X)$. These relations define degrees of association between elements of the same set, and are referred to as *directed graphs* because they can be easily represented by diagrams where:

- each element of X is uniquely depicted by a single node (or vertex)
- directed connections (or edges) between nodes indicate a non-zero degree of association for pairs of elements of X in the relation
- each such connection is uniquely defined by its particular association value.

2.1.4 Properties of Graphs

In this case, relations are represented by matrices of dimension $n \times n$, that is, there are n^2 possible connections between the n elements of the directed graph. In particular, the degrees of association between x_i and $x_j \in X$, $R(x_i, x_j)$ might be different than $R(x_j, x_i)$, hence the direction of associations.

A binary fuzzy relation $R(X, X)$ is *reflexive* iff $R(x, x) = 1$ for all $x \in X$. That is, if every element of X is maximally associated with itself. A binary fuzzy relation $R(X, X)$ is *symmetric* iff $R(x, y) = R(y, x)$ for all $x, y \in X$. That is, if x is associated with y to a degree, then y is associated with x to the same degree, thus establishing *non-directed graphs* whose defining matrices are symmetrical relations require only $(n^2 - n)/2$ elements to be defined.

A binary fuzzy relation $R(X, X)$ is (max-min) *transitive* iff:

$$R(x, z) \geq \max_{y \in X} \min[R(x, y), R(y, z)]$$

for all $x, z \in X$. This definition generalizes the crisp transitive property which requires that (x, z) be related if (x, y) and (y, z) are related, by requiring that (x, z) be related at least to the maximum of the degrees of association obtained from performing the minimum of (x, y) and (y, z) for all other y in X . That is, for each indirect connection between x and z through some y , the weight of the connection is the lowest of each connection (x to y and y to z). Finally, the weight of the connection between x and z , must be larger than the largest of all indirect connections through all y .

2.1.5 Composition of Graphs

The composition of binary relations defined on the same set is performed by composition of the matrices that define them. The logical composition of matrices is performed in the same way as the numerical counterpart, except that multiplication and summation are substituted by logical operations. In the present work, we substitute multiplication and summation by the AND and OR operations respectively. The standard definition, though many others exist, of OR and AND in fuzzy logic is the maximum and minimum operations respectively. Thus, the standard composition of fuzzy graphs is referred to as the *max-min composition*:

$$R \circ R = \max_k \min(r_{ik}, r_{kj}) = r'_{ij}$$

where r_{ij} denotes $R(x_i, x_j)$.

2. 1.6 Transitive Closure

The *transitive closure* of a relation $R(X, X)$ is defined as the relation that is transitive, contains $R(X, X)$, and whose elements have the smallest possible membership weights that still allow the first two requirements to be met. In other words, the transitive closure of a relation yields a relation where all pairs of elements which were directly or indirectly related in the original relation, are now directly related with a weight which is the maximum of the set of minimally associated paths via all possible third elements. The algorithm to obtain the transitive closure R_T of R consists of the following three steps (Klir & Yuan 1995):

1. $R' = R \cup (R \circ R)$.
2. If $R' \neq R$, make $R = R'$ and go back to step 1.
3. Stop: $R_T = R'$.

Where $(R \circ R)$ represents the composition of matrices in 2.1.5.

2.1.7 Similarity Relations

A binary fuzzy relation $R(X, X)$ is a similarity relation if it is reflexive, symmetric, and transitive. These relations are also known as *equivalence relations*.

2.1.8 Proximity Relations

A binary fuzzy relation $R(X, X)$ is a proximity relation if it is reflexive and symmetric. These relations are also known as *compatibility relations*. The transitive closure of a proximity relation is a similarity relation. See figures 1 and 2.

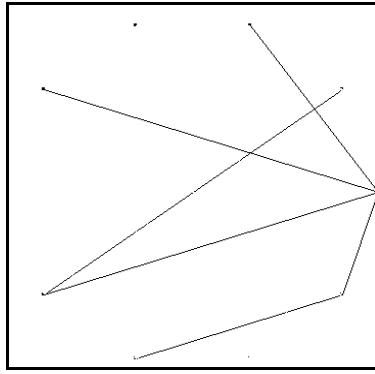

Figure 1: Proximity relation with 7 elements

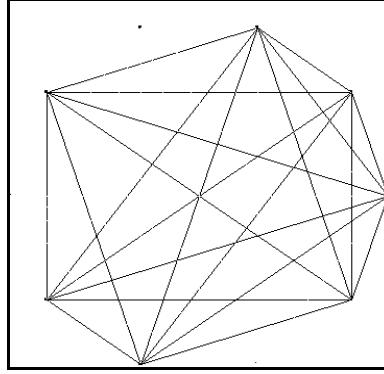

Figure 2: The similarity relation obtained from the transitive closure of the relation in figure 1

Proximity relations are very important to express relationships in databases (Shenoi & Melton 1989). They require reflexivity (elements are associated with themselves) and are symmetrical, that is, they define reflexive non-directed graphs which can capture effectively users' expert knowledge without requiring transitivity.

2.2 Proximity Relations as Co-Occurrence Probabilities

The datasets described in 1 are binary relations between two sets. For instance, **PEOPLE_DOCUMENTS1** and **PEOPLE_DOCUMENTS2** are binary relations A between the set P of n people names and the set D of m documents in the database. Specifically, these relations are also crisp since they specify if a person p occurs (1) or not (0) in a document d , that is $A(p, d) = 1$ or $A(p, d) = 0$.

To discern closeness between people according to the documents they occur in, we compute the *People Document Proximity (PDP)*, obtained from A by the following formula:

$$PDP(p_i, p_j) = \frac{\sum_{k=1}^m (a_{i,k} \wedge a_{j,k})}{\sum_{k=1}^m (a_{i,k} \vee a_{j,k})} = \frac{N_{\cap}(p_i, p_j)}{N(p_i) + N(p_j) - N_{\cap}(p_i, p_j)} \quad (1)$$

The proximity between two persons, p_i and p_j , is the probability that both p_i and p_j co-occur in the same document. It depends on the sets of documents where each person occurs, and the intersection of these sets. $N(p_i)$ is the number of documents person p_i occurs in, and $N_{\cap}(p_i, p_j)$ the number of documents both persons co-occur in. This last quantity is the number of elements in the intersection of the sets of documents that each person occurs in. Thus, two persons are near if they tend to occur in many of the same documents.

Similarly, we can obtain the complementary proximity measure from the same relation A between People and Documents: the Document People Proximity (DPP):

$$DPP(d_i, d_j) = \frac{\sum_{k=1}^n (a_{k,i} \wedge a_{k,j})}{\sum_{k=1}^n (a_{k,i} \vee a_{k,j})} = \frac{N_{\cap}(d_i, d_j)}{N(d_i) + N(d_j) - N_{\cap}(d_i, d_j)} \quad (2)$$

This proximity, defined on the set of Documents D, captures the probability that two documents d_i and d_j mention the same person. It depends on the sets of people mentioned in each document, and the intersection of these sets. $N(d_i)$ is the number of persons mentioned in document d_i , and $N_{\cap}(d_i, d_j)$ the number of people mentioned in both documents. Thus, two documents are near if they tend to mention many of the same people.

In general, given a binary relation R between sets X (of n elements x) and Y (of m elements y), we extract two complementary proximity relations: XYP and YXP . $XYP(x_i, x_j)$ is the probability that both x_i and x_j are related in R to the same element $y \in Y$. Conversely, $YXP(y_i, y_j)$ is the probability that both y_i and y_j are related in R to the same element $x \in X$. The respective formulas are:

$$XYP(x_i, x_j) = \frac{\sum_{k=1}^m (r_{i,k} \wedge r_{j,k})}{\sum_{k=1}^m (r_{i,k} \vee r_{j,k})}; \quad YXP(y_i, y_j) = \frac{\sum_{k=1}^n (r_{k,i} \wedge r_{k,j})}{\sum_{k=1}^n (r_{k,i} \vee r_{k,j})} \quad (3)$$

Notice that these formulas do not require R to be a crisp binary relation; it could be a fuzzy binary relation, for instance, the normalized frequency of occurrence of a keyword in a document.

Other measures of probability can be used to discern closeness between elements of two sets in a binary relation. In information retrieval it is common to use conditional probabilities, for instance in the *Pointwise Mutual Information* technique (Turney 2001). In this case, we do not obtain a proximity relation since conditional probabilities are not symmetric. Such a measure of closeness is calculated for the elements of X and Y as P_X and P_Y :

$$P_X(x_i, x_j) = P(x_i | x_j) = \frac{\sum_{k=1}^m (r_{i,k} \wedge r_{j,k})}{\sum_{k=1}^m (r_{j,k})}; \quad P_Y(y_i, y_j) = P(y_i | y_j) = \frac{\sum_{k=1}^n (r_{k,i} \wedge r_{k,j})}{\sum_{k=1}^n (r_{k,j})} \quad (4)$$

P_X is the probability that x_i is related in R to an element $y \in Y$, given that x_j is related in R to the same y . Conversely, P_Y is the probability that y_i is related in R to the an element $x \in X$, given that y_j is related in R to to the same x . P_X and P_Y , in general, are not symmetric, therefore they are not proximity relations, though they also capture a measure of association or closeness between elements of X and Y respectively. They are related to the proximity measures extracted from a binary relation R in the following way:

$$XYP(x_i, x_j) = \frac{1}{\frac{1}{P_X(x_j, x_i)} + \frac{1}{P_X(x_i, x_j)} - 1}; \quad YXP(y_i, y_j) = \frac{1}{\frac{1}{P_Y(y_j, y_i)} + \frac{1}{P_Y(y_i, y_j)} - 1} \quad (5)$$

For characterizing associations in relations extracted from databases, we prefer the proximity measure of association as defined in formula 3, over the conditional probabilities of formula 4, because P_X and P_Y can imply a strong degree of association (or closeness) between two elements, when that association is one-sided only. Specifically, using P_X as the measure of association, if, $N(x_j)$, the set of elements of Y related to x_j , is largely contained in $N(x_i)$, then $P_X(x_i, x_j)$ is large, implying a strong degree of association between x_i and x_j . But if, $N(x_i)$, is much larger than $N(x_j)$, then $P_X(x_j, x_i)$ is small, implying a weak degree of association between x_j and x_i .

In many applications, when we think of a strong association between two elements, we expect both directions of association to be similar. In other words, if x_i is strongly associated with x_j , then we expect x_j to be strongly associated with x_i . Therefore, in such cases, the proximity measures are a more intuitive measurement of association or closeness between elements. This is the case of the current application, where, for instance, we wish to discover which persons are more associated with each other. To consider that two persons are very associated, we want them to be related to evidential items (such as documents, events, groups) in much the same way. This means that a person who is only related to a subset of such items that another person is related to, should not be considered very close to the latter. Thus, the proximity measure is a more intuitive measure of this degree of association.

2.3 Extracting Proximity Relations from the Datasets

From all the datasets described in 1, **PEOPLE_DOCUMENTS1**, **CITIES_DOCUMENTS1**, **PEOPLE_DOCUMENTS2**, **EVENTS_GROUPS**, **EVENTS_PEOPLE**, **GROUPS_PEOPLE**, and **PEOPLE RELATED PEOPLE**, using formula 3, Eugene Gavrilov generated the proximity measures

PDP1, **CDP1**, and **PDP2**, and Jim Gattiker generated the proximity measures **EGP**, **GEP**, **EPP**, **PEP**, **GPP**, **PGP**, **PRP**, and **RPP**. Following the notation used in formula 3, when constructing the name of a proximity measure, the first letter denotes the first set in the relation (e.g. **P** from “People” in **PEOPLE_DOCUMENTS1**), the second letter denotes the second set in the relation (e.g. **D** from “Documents” in **PEOPLE_DOCUMENTS1**), and the third letter is always **P** for “proximity”.

3. ANALYSIS OF PROXIMITY GRAPHS

3.1 NetStat

After computing **PDP1**, we noticed that the name of "Osama Bin Laden" was associated with most every other name in the data set, therefore we decided to delete this name from the analysis. The set of People Names contains 145 entries.

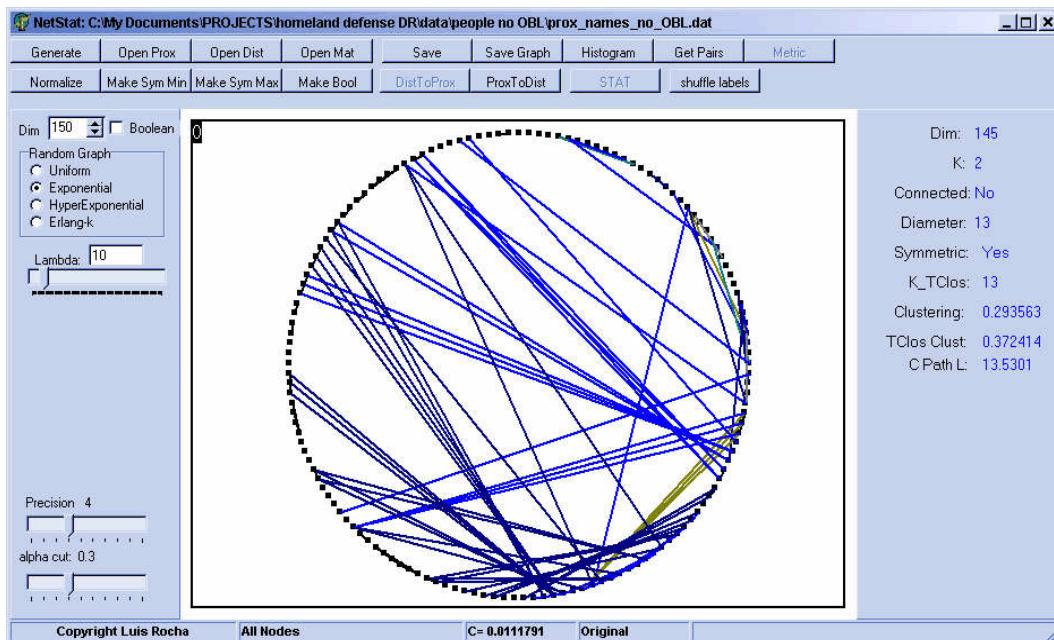

Figure 3: Netstat screen showing all links over 0.3 of **PDP1**

We developed prototype software to analyze proximity graphs: NETSTAT. Figure 3 shows the main screen of this program. It displays all nodes of a proximity graph in a circle. Each node can be clicked to display the links of a given node. It allows the user to specify the lower value of all links shown. For instance, in Figure 3, all links in PDP1 with proximity value ≥ 3 are displayed and color coded for intensity. NETSTAT, also calculates many other graph theoretic data, such as the diameter of the graph (the longest path, in number of links, between two nodes), which is 13 in this case, the average number of neighbor nodes ($K=2$ in this case), etc. This can be seen in figure 3 on the left side panel. It also calculates the transitive closure of proximity graphs (which thus become similarity graphs), as seen in Figure 4.

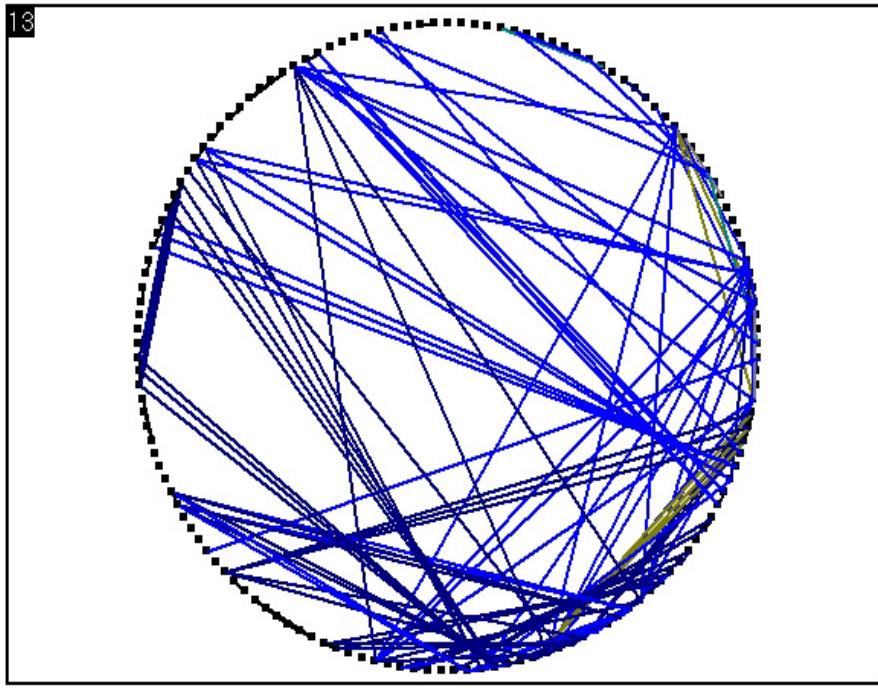

Figure 4: Transitive closure of **PDP1**, showing all links ≥ 3 .

NETSTAT also outputs in text the pairs of items shown in a proximity graph. Figure 5 shows the text output window for **FPD1** for pairs with proximity ≥ 3 . All Pairs of people names in **PDP1** with proximity ≥ 3 are included in appendix A.1. We recall that these values of proximity denote the probability of co-occurrence of two names in the documents in the database. Naturally, NetStat also produces the list of pairs of items in the transitive closure of proximity graphs. In appendix A.2, the pairs of people names whose transitive closure of PDP1 is greater or equal to 3 are displayed.

All values with $\mathbf{PDP1} \geq 0$ are plotted in figure 6. We have also calculated that the distribution of proximity values shown in figure 6, passes a χ^2 test for an exponential random distribution² with $\lambda = 4.6$.

We conducted exactly the same analysis for the remaining proximity graphs, with the results listed in appendix A.

²The exponential probability distribution function is $F(t) = \lambda e^{-\lambda t}$, $t \geq 0$, $\lambda > 0$.

3.2 Comparison with PEOPLE_DOCUMENTS1 Subset used by Lattice Group

Cliff Joslyn and Susan Mniszewski analyzed a subset of the PEOPLE_DOCUMENTS1 relation containing the following 36 people and 16 document subsets:

$$\mathcal{P} = \{ \text{Abdelsattar Dahmane, Abdullah Ahmed Abdullah, Abu Bakar Bashir, Abu Qatada, Ahmad Shah Masud, Ahmed Ressam, Anas al-Liby, Ayman aL-Zawahiri, Bouraoui El-Ouaer, Faiz Abu Bakar Bafana, Fateh Kamel, Fathur Rohman al-Ghozi, Jamal al-Fadal, Mohamad Khalim bin Jaffar, Mohamed Sliti, Mohammed Saddiq Odeh, Mohammed bin Laden, Muammar Abu Minyar Al-Qadhafi, Muhammad Atef, Mustapha Labsi, Omar Bakri Mohammed, Osama Bin Laden, Richard Reid, Riduan Isamuddin, Saif Al-Adel, Shaykh Ahme Nur Jimale, Sheikh Omar Abd al-Rahman, Sulaiman Abu Ghaith, Tarek Maaroufi, Victor Bout, Yacine Aknouche, Yasin al-Qadi, Yasir al-Sirri, Youssef Nada, Zacarias Moussaoui, Zayn-al-Abidin Abu-Zubaydah} \}$$

$$\mathcal{D} = \{ 3, 13, 52, 54, 56, 59, 137, 144, 149, 153, 160, 294, 449, 537, 636, 662 \}$$

We calculated the people proximity ($\mathbf{PDP1}_{\text{sub}}$) and document proximity ($\mathbf{DPP1}_{\text{sub}}$) for this subset, as provided by Cliff Joslyn and Susan Mniszewski, of the PEOPLE_DOCUMENTS1 Relation. Figure

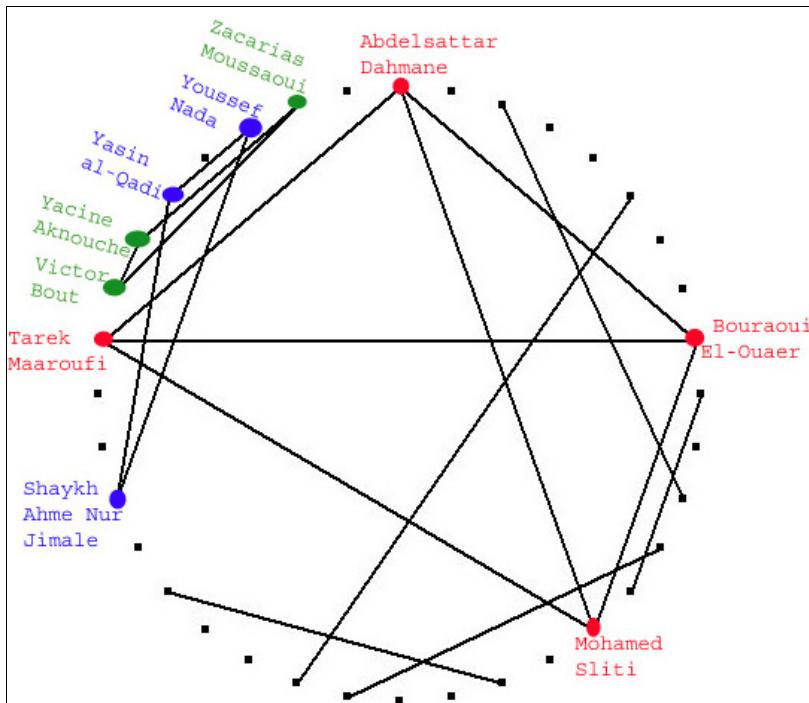

Figure 7: $\mathbf{PDP1}_{\text{sub}}$ showing only links with proximity = 1

7 shows PDP1_{sub} for those links with maximum proximity (1). These are people names who appear in exactly the same documents (and only in those). Figure 7 highlights 3 groups of people (one with 4 people, the other with 3).

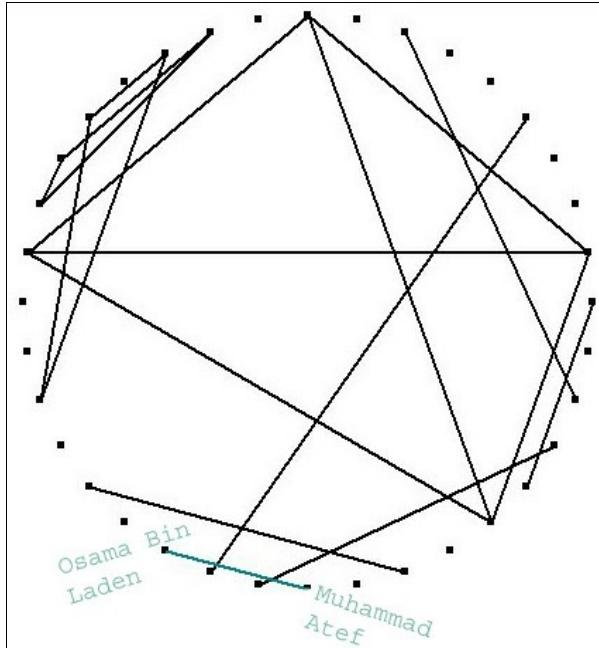

Figure 8: PDP1_{sub} showing only links with proximity ≥ 0.5

Figure 8 depicts the same graph, but now showing all links with proximity ≥ 0.5 ; another link appears. Figure 9 depicts the same graph, showing all links with proximity ≥ 0.4 ; Many more links appear.

While the graphs in figures 7 and 8 (prox = 1, and prox ≥ 0.5) are naturally transitively closed, the one in Figure 9 is not. Figure 10 depicts the transitive closure of PDP1_{sub} showing links with proximity ≥ 0.4 .

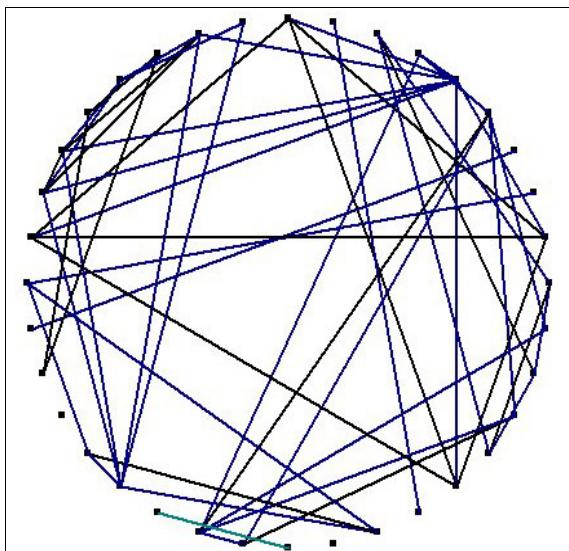

Figure 9: PDP1_{sub} showing only links with proximity ≥ 0.4

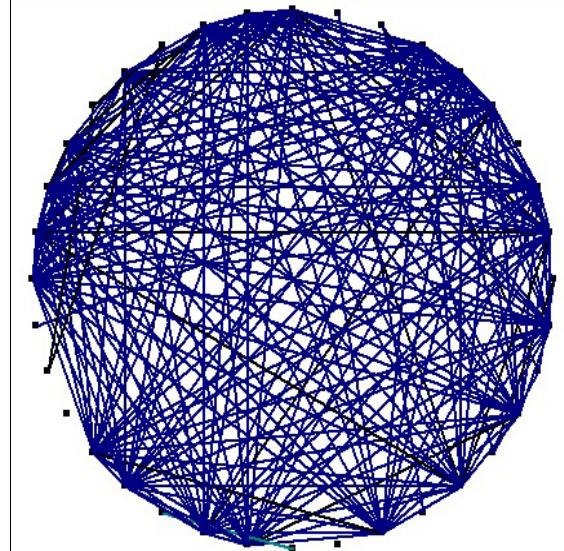

Figure 10: Transitive Closure of PDP1_{sub} showing links with proximity ≥ 0.4 .

We repeated the same process with DPP1_{sub} , which denotes the probability that two documents Figure 11 depicts DPP1_{sub} (left) and its transitive closure (right) showing all links with proximity ≥ 0.4 .

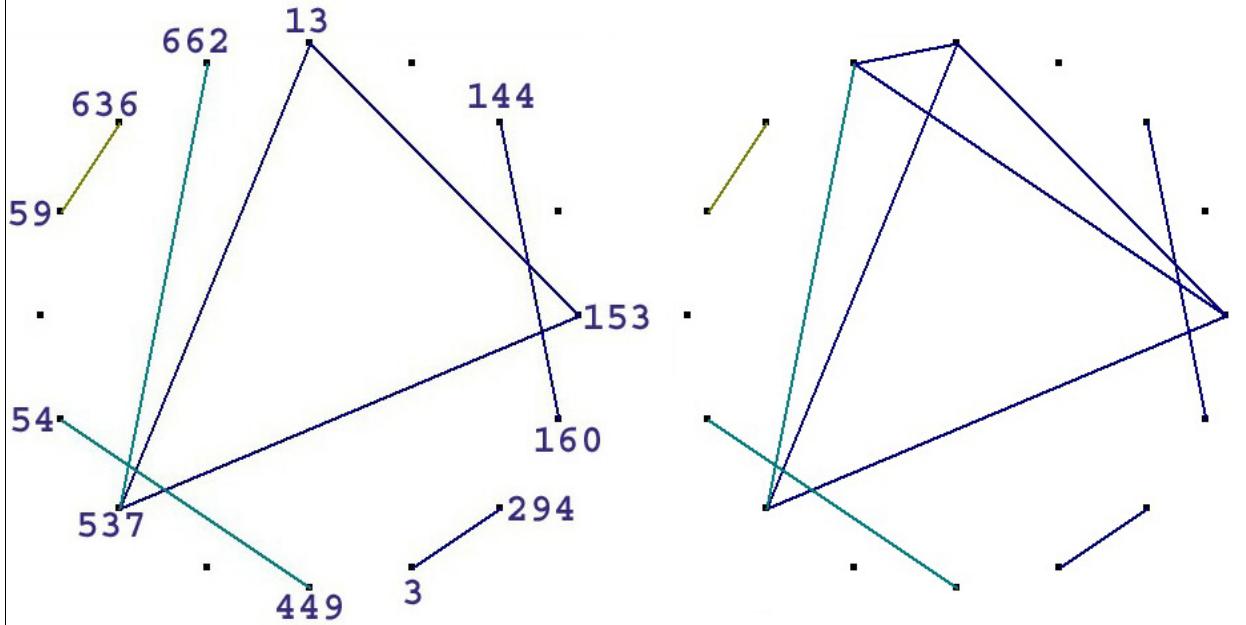

Figure 11: DPP1_{sub} (left) and its transitive closure (right) showing all links with proximity ≥ 0.4 .

After this first iteration to compare the proximity graphs with the lattice approach, we posit that, co-occurrence proximity graphs capture all of the information that lattices do as well as additional information. Given a relation R between two sets X and Y , the complementary proximity graphs XYP and YXP , one obtains using formula 3, capture all co-occurrence information among the elements of set X and set Y respectively. A lattice path between two elements of X via an element of Y must exist as a co-occurrence probability, that is a link, in the XYP graph (and vice versa). Furthermore, proximity graphs allow us to grasp levels of co-occurrence probability, which lattice representations do not. In a proximity graph, we can choose to visualize only the links above a given $\alpha \in [0, 1]$.

However, a lattice representation may offer an alternative view of the R relation in a single graph, as opposed to the two distinct XYP and YXP graphs. In particular, given the complexity of lattice graphs with many elements, a lattice representation may be an interesting analysis tool to visualize a subset of nodes of interest in large proximity graph.

4. SEMI-METRIC BEHAVIOR OF PROXIMITY GRAPHS

4.1 From Proximity to Distance

From the inverse of the generic proximity measures XYP and YXP , obtained from a relation R between sets X and Y using formula 3, we can compute a generic distance function among the elements of X or Y :

$$d_X(x_i, x_j) = \frac{1}{XYP(x_i, x_j)} - 1; \quad d_Y(y_i, y_j) = \frac{1}{YXP(y_i, y_j)} - 1 \quad (6)$$

d_X and d_Y are distance functions because they are nonnegative, symmetric, real-valued functions such that $d(x, x) = 0$ (Shore & Sawyer 1993). They define two weighted graphs D_X and D_Y , which we refer to as *distance graphs*, whose vertices are all of the elements of X or Y , and the edges are the values of $d_X(x_i, x_j)$ and $d_Y(y_i, y_j)$, respectively. A small distance between elements implies a strong association between them.

4.2 Semi-metric behavior: latent associations

The distance graphs D obtained from applying distance function d (formula 6) to proximity graphs, are not Euclidean because, for a pair of elements of X (or Y) x_1 and x_2 , the triangle inequality may be violated: $d(x_1, x_2) \leq d(x_1, x_3) + d(x_3, x_2)$ for some element x_3 . This means that the shortest distance between two elements in D may not be the direct link but rather an indirect pathway. Such distance functions are referred to as semi-metrics (Galvin & Shore 1991).

Naturally, the distance graphs obtained from applying a distance function such as d can be made Euclidean. If we compute the transitive closure of the respective proximity, we would obtain a similarity relation on the set of keywords. The application of distance d (formula 6) to a similarity graph would result in a metric distance graph. Indeed, it is very common in the analysis of social or document networks to impose a metric requirement on the distance graphs generated. However, we have compiled evidence elsewhere (Rocha 2002) that loosening the metric requirement, results in a methodology capable of identifying important associations between the elements of proximity graphs obtained from a relation R .

Specifically, those pairs of elements with larger semi-metric behavior (those which possess at least one indirect path between them whose distance is much shorter than the direct link) denote a *latent* association. That is, an association which is not grounded on direct evidence provided by the relation R , but rather implied by the overall network of associations in this relation. More formally, when $d(x_i, x_j) \ll d(x_i, x_k) + \dots + d(x_l, x_m) + \dots + d(x_p, x_j)$, then the pair (x_i, x_j) possesses a latent association in distance graph D .

What a latent association means depends on the semantics of the application. For instance, in graphs of keyword co-occurrence in documents, a latent association is associated with novelty and can be used to identify trends (Rocha 2002). In the case of terrorist networks, a latent association may identify pairs of people, groups, etc. for which we do not have direct evidence, in the available documents, that a real association exists, but who could easily be indirectly associated.

4.3 Characterizing Semi-metric behavior

Clearly, semi-metric behavior (or latency) is a question of degree. For some pairs of vertices the indirect distance provides a much shorter short-cut, a larger reduction of distance, than for others. One way to capture this property of pairs of semi-metric vertices is to compute a *semi-metric ratio*:

$$s(x_i, x_j) = \frac{d_{\text{direct}}(x_i, x_j)}{d_{\text{shortest}}(x_i, x_j)} \quad (7)$$

where d_{shortest} is the shortest, direct or indirect, distance between the pair of elements. s is positive and ≥ 1 for semi-metric pairs. Given that larger graphs tend to show a much larger spread of distance, s tends to increase with the number of vertices of D . Therefore, to be able to compare semi-metric behavior between different distance graphs, a *relative semi-metric ratio* is used:

$$rs(x_i, x_j) = \frac{d_{\text{direct}}(x_i, x_j) - d_{\text{shortest}}(x_i, x_j)}{d_{\max} - d_{\min}} \quad (8)$$

rs compares the semi-metric distance reduction to the maximum possible distance reduction in graph D . d_{\max} is the largest direct distance in the graph, and $d_{\min} = 0$ is the shortest distance in the entire graph. This ratio varies between 0 and 1 for semi-metric pairs, and it is negative for metric pairs.

Often, the direct distance between two elements is ∞ because they do not relate to any common elements in the other set of relation R . As a result, s and rs are also ∞ for these cases. Thus, s and rs are not capable of discerning semi-metric behavior for pairs that do not have an initial finite direct distance. To detect relevant instances of this infinite semi-metric reduction, we define the *below average ratio*:

$$b(x_i, x_j) = \frac{\overline{d}_{x_i}}{d_{\text{shortest}}(x_i, x_j)} \quad (9)$$

where \overline{d}_{x_i} represents the average direct distance from x_i to all x_k such that $d_{\text{direct}}(x_i, x_k) \geq 0$. b is only applied to semi-metric pairs of elements (x_i, x_j) where $d_{\text{shortest}}(x_i, x_j) < d_{\text{direct}}(x_i, x_j)$ and it measures how much the shortest indirect distance between x_i and x_j falls below the average distance of all

elements x_k directly associated with element x_i . Note that $b(x_i, x_i) \neq b(x_j, x_i)$. Of course, b can also be applied to pairs with finite semi-metric reduction. $b > 1$ denotes a below average distance reduction.

The ratios from formulas 7 to 9 allow us to identify individual pairs of elements with large semi-metric behavior – latent pairs. However, we can also characterize entire distance graphs as to their semi-metric behavior. To do this, we compute the ratio of pairs in a distance graph D with $rs > 0$, denoted by π , and those with $b > 1$, denoted by β . Another measure (see (Rocha 2002) for more details), is the mean value of rs of the top 1% pairs with $rs > 0$ in a given distance graph D . In other words, we rank all pairs in D according to rs , and then selected the top 1%³. We denote by μ the mean value of rs in this set. A metric distance graph yields $\pi=0$, $\beta=0$, and $\mu=0$. For semi-metric distance graphs, these ratios vary in the unit interval.

5 ANALYSIS OF SEMI-METRIC BEHAVIOR IN DATASETS: CAPTURING INDIRECT AND LATENT ASSOCIATIONS

5.1 Semi-metric behavior of Distance Graphs

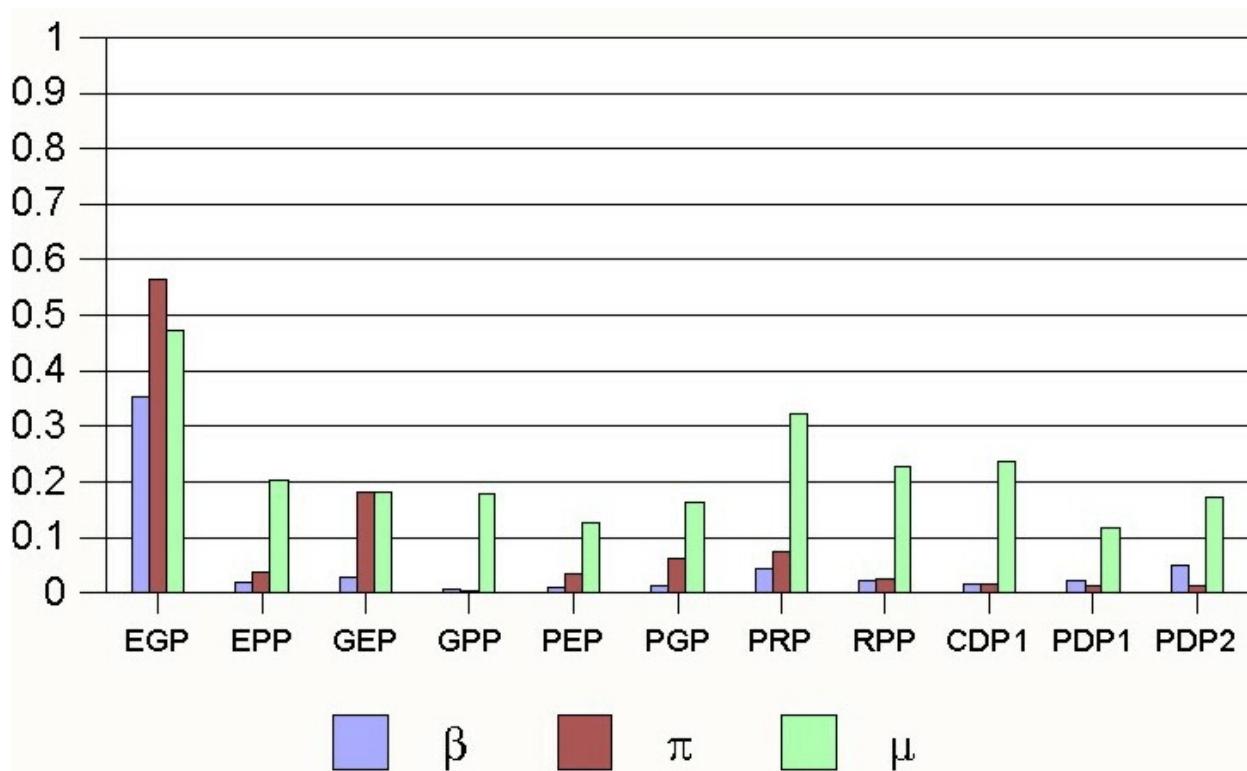

Figure 12: Semi-metric behavior of all data sets

³Not 1% of the set of semi-metric pairs, but 1% of all pairs in D .

We can now compare the different distance graphs obtained from the data sets according to π , β , and μ . π and β quantify the existence of semi-metric behavior in a distance graph. Specifically, π captures the ratio of pairs with finite direct distance, which possess at least a shorter indirect path. While β captures the ratio of pairs with finite or infinite direct distance, which possess at least one indirect path shorter than the average of all direct paths to one of the elements of the pair. The parameter μ captures the strength of the type of semi-metric behavior capture by π (see details in (Rocha 2002)). Figure 12 depicts a bar plot of these three parameters for the distance graphs obtained for each proximity graph produced in section 2.3. Table 1 shows the actual numerical values. We can see that most distance graphs possess very little semi-metric behavior. π and β are small for most of them. For instance, the distance graph obtained from **PDP2**, contains only 1.2% of pairs with $rs > 0$, and 4.8% with $b > 1$. This means that very few pairs of people names have shorter indirect distances, thus, there is not much latent information in the documents used to generate **PDP2**. Most people names who can be associated have been identified in the documents. The datasets that are most semi-metric, thus with largest number of indirect or latent pairs, are the distance graphs obtained from **EGP** and **GEP**.

Table 1: Semi-metric behavior parameters for all data sets

	EGP	EPP	GEP	GPP	PEP	PGP	PRP	RPP	CDP1	PDP1	PDP2
β	0.3526	0.0192	0.0273	0.0057	0.0082	0.0137	0.0424	0.0236	0.0172	0.0216	0.0481
π	0.5641	0.0385	0.1818	0.0043	0.0337	0.0606	0.0742	0.0254	0.0157	0.0125	0.0124
μ	0.4713	0.2021	0.1815	0.1793	0.1273	0.1619	0.3219	0.2292	0.2378	0.1166	0.173

But in addition to the quantity of semi-metric pairs, we need to describe the strength of semi-metric behavior. Parameter μ captures that factor. Notice that we can easily obtain a distance graph with many semi-metric pairs (large π and β), but with very low values of rs and b , thus weak latency. This is the case of most random graphs (see Rocha (Rocha 2002)). One way to compare several distance according to both quantity and strength of latent (semi-metric) behavior, is to plot the values of μ and π in a two-dimensional plane, as depicted in Figure 13. The first parameter quantifies the existence of *strong latent associations*, whereas the second quantifies the *quantity of latent associations* – or how further away from metric the distance graph is. A metric distance graph would occupy the origin of this space. The further away from the origin a distance graph is, the more we can consider it to denote *incomplete knowledge*. For instance, if the **PDP2** graph were further away from the origin, we would say that the documents in the database were missing many, strong, latent associations between people.

5.2 Identification of Latent Pairs

From an analysis standpoint, after calculating the semi-metric behavior of the distance graph of a given dataset, one is naturally interested in identifying the specific pairs of elements that are most semi-metric – those with higher latency. These are pairs of elements (e.g. people names) whose strong association does not possess direct evidence in a given relation (e.g. co-occurrence in

documents), but is rather implied by the overall associative network obtained from the relation. We can say that a strong latent association between pairs of elements is a global property of the network.

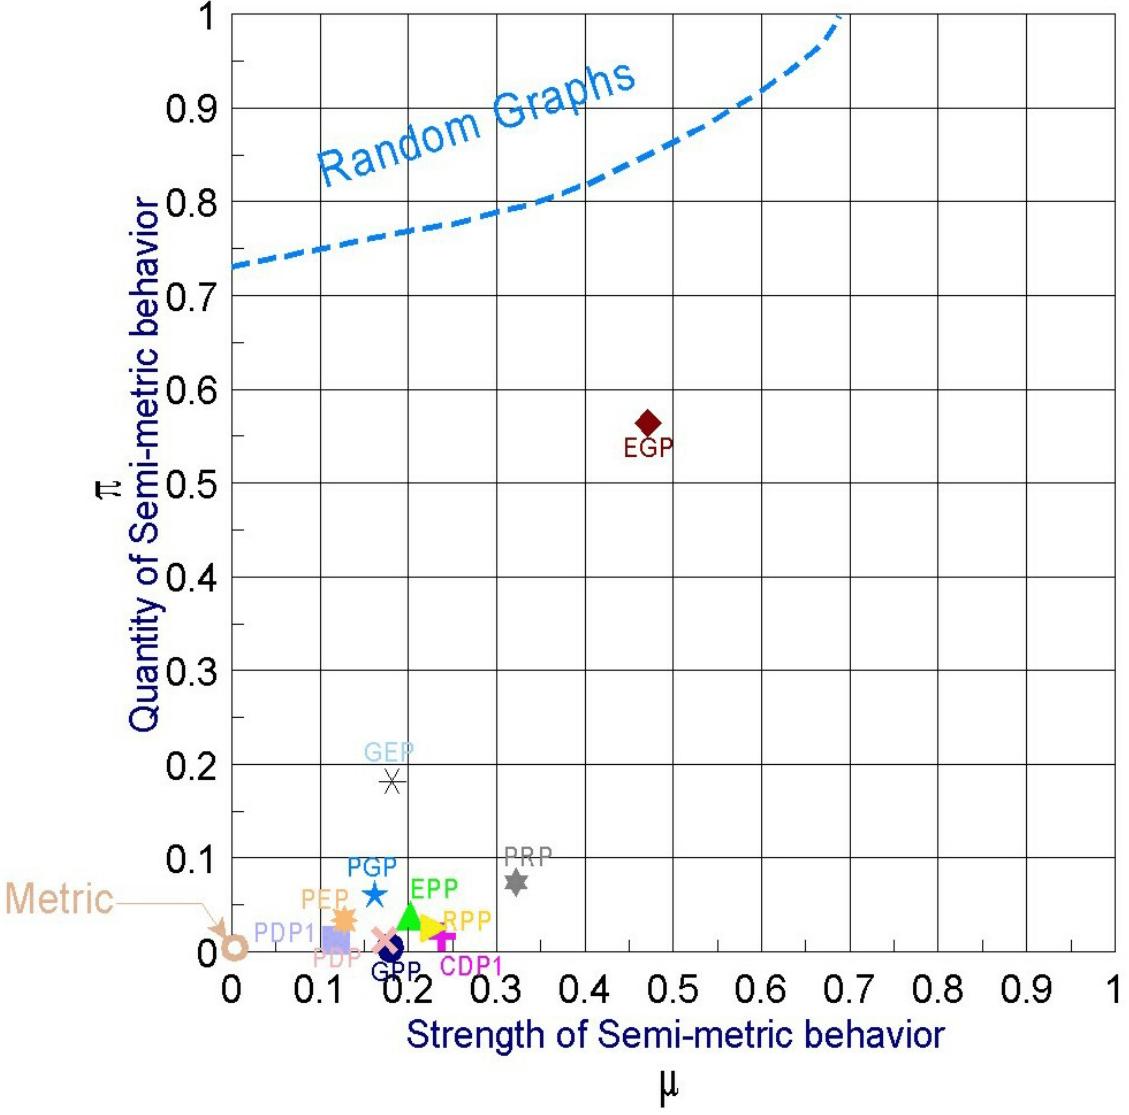

Figure 13: Plot of all data sets in μ and π plane.

In Appendix B, the top semi-metric pairs for the distance graphs obtained from all the proximity relations produced in section 2.3 are listed. We list only those pairs for which $s \geq 2$ (pairs of elements which possess at least one indirect path half as short as the direct distance between them), $rs \geq 0.25$ (pairs of elements which possess at least one indirect path which reduces the distance between them by at least 25% of the largest possible direct distance in the graph), or $b \geq 2$ (pairs of elements which possess at least one indirect path half as short as the average distance to all elements directly connected to one of the elements in the pair). These values are somewhat arbitrary, but were chosen to pick up pairs with substantial semi-metric behavior.

5.3 Comparison with Lattice Subset

In section 3.2 we calculated the people proximity (PDP1_{sub}) and document proximity (DPP1_{sub}) for a subset of the PEOPLE_DOCUMENTS1 Relation. We compared the information one gets from applying the proximity analysis with the lattice methodology. We also calculated the most semi-metric pairs in the distance graphs obtained from PDP1_{sub} and DPP1_{sub} . Figure 14 depicts PDP1_{sub} with two semi-metric pairs highlighted.

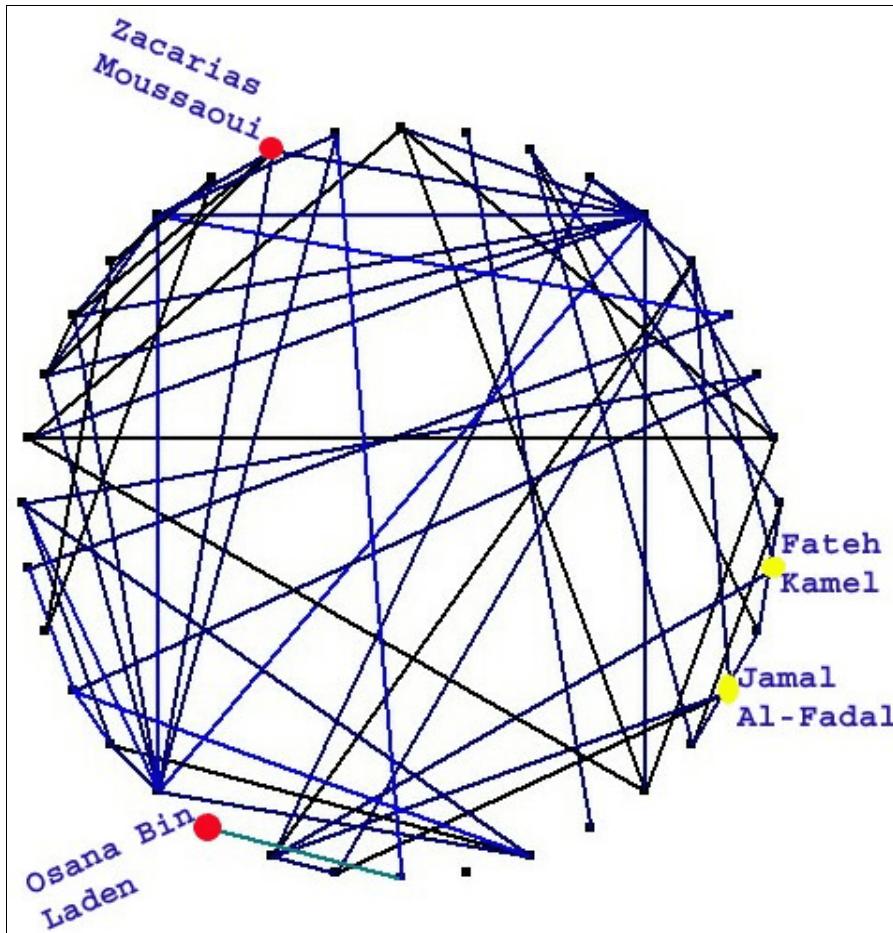

Figure 14: PDP1_{sub} showing links with proximity ≥ 0.3 . The pair with highest s is highlighted in red and the pair with highest b is highlighted in yellow

Specifically, below are the top semi-metric pairs:

Pairs from PDP1_{sub} with $s \geq 2$

Osama Bin Laden, Yacine Aknouche: 2.9461
 Osama Bin Laden, Zacarias Moussaoui: 2.9461

Osama Bin Laden, Riduan Isamuddin: 2.9461
 Mohammed bin Laden, Osama Bin Laden: 2.9461
 Osama Bin Laden, Victor Bout: 2.9461
 Fathur Rohman al-Ghozi, Osama Bin Laden: 2.8702
 Abu Bakar Bashir, Osama Bin Laden: 2.8702
 Ahmad Shah Masud, Osama Bin Laden: 2.8125
 Muhammad Atef, Richard Reid: 2.6667
 Muhammad Atef, Yasir al-Sirri: 2.6667
 Osama Bin Laden, Sheikh Omar Abd al-Rahman: 2.4337
 Fateh Kamel, Osama Bin Laden: 2.2094
 Mustapha Labsi, Osama Bin Laden: 2.2094
 Jamal al-Fadal, Osama Bin Laden: 2.2094

Pairs from PDPI_{sub} with $rs \geq 0.25$

Ahmad Shah Masud, Osama Bin Laden: 0.6444
 Osama Bin Laden, Zacarias Moussaoui: 0.6162
 Osama Bin Laden, Yacine Aknouche: 0.6162
 Osama Bin Laden, Riduan Isamuddin: 0.6162
 Mohammed bin Laden, Osama Bin Laden: 0.6162
 Osama Bin Laden, Victor Bout: 0.6162
 Abu Bakar Bashir, Osama Bin Laden: 0.6078
 Fathur Rohman al-Ghozi, Osama Bin Laden: 0.6078
 Osama Bin Laden, Sheikh Omar Abd al-Rahman: 0.5495
 Mustapha Labsi, Osama Bin Laden: 0.5106
 Jamal al-Fadal, Osama Bin Laden: 0.5106
 Fateh Kamel, Osama Bin Laden: 0.5106
 Mohammed Saddiq Odeh, Osama Bin Laden: 0.4327
 Muammar Abu Minyar Al- Qadhafi, Osama Bin Laden: 0.4078
 Muhammad Atef, Richard Reid: 0.3334
 Muhammad Atef, Yasir al-Sirri: 0.3334

Pairs from PDPI_{sub} with $b \geq 2$

Fateh Kamel, Jamal al-Fadal: 2.3741
 Mustapha Labsi, Fateh Kamel: 2.3741
 Fateh Kamel, Mustapha Labsi: 2.3741
 Jamal al-Fadal, Fateh Kamel: 2.3741
 Riduan Isamuddin, Victor Bout: 2.2138
 Mohammed bin Laden, Victor Bout: 2.2138
 Mohammed bin Laden, Yacine Aknouche: 2.2138
 Mohammed bin Laden, Zacarias Moussaoui: 2.2138
 Riduan Isamuddin, Zacarias Moussaoui: 2.2138
 Riduan Isamuddin, Yacine Aknouche: 2.2138
 Osama Bin Laden, Victor Bout: 2.1198
 Osama Bin Laden, Yacine Aknouche: 2.1198
 Osama Bin Laden, Zacarias Moussaoui: 2.1198
 Osama Bin Laden, Riduan Isamuddin: 2.1198
 Osama Bin Laden, Mohammed bin Laden: 2.1198
 Osama Bin Laden, Abu Bakar Bashir: 2.0652
 Osama Bin Laden, Fathur Rohman al-Ghozi: 2.0652

Pairs from DPPI_{sub} with s ≥ 2

52, 144: 2.6668
54, 636: 2.4384
3, 54: 2.3078
54, 56: 2.3078
54, 59: 2.2767
54, 537: 2.2767
153, 636: 2.2499
54, 153: 2.1182

Pairs from DPPI_{sub} with rs ≥ 0.25

54, 636: 0.5899
54, 153: 0.4872
52, 144: 0.4806
54, 59: 0.4745
54, 537: 0.4745
54, 56: 0.4358
3, 54: 0.4358
153, 636: 0.3844
52, 294: 0.3273
13, 52: 0.308
52, 149: 0.308
54, 137: 0.282
153, 537: 0.2691

Pairs from DPPI_{sub} with b ≥ 2

None.

6 CONFIDENCE IN RESULTS: CAPTURING LATENT KNOWLEDGE

The links in proximity graphs represent an observable and meaningful quantity, namely the co-occurrence of pairs of elements of one set in elements of another set related by binary relation. But the semi-metric behavior of these pairs of elements, as calculated by formulas 7 to 9, does not possess such an obvious meaning.

In section 5 we identified semi-metric behavior with latent knowledge. That is, semi-metric pairs of elements may denote a real association between the elements, but one which is not directly corroborated by available evidence (in the relation under scrutiny). In this sense, semi-metric pairs may denote missing evidence or knowledge. To understand if this is the case we conducted two different types of tests: an expert test, to identify if semi-metric pairs imply real associations, and a random deletion test, to characterize how well semi-metric recover lost knowledge. The next two sub-sections describe these tests in detail.

6.1 Expert Test

From **PDP1**, we extracted the top 100 pairs of people names with highest rs and the top 200 pairs of people names with highest b . We then generated several random graphs with the same people names as **PDP1**. Specifically, we generated the following 10 random proximity graphs:

- 4 graphs obtained from randomly shuffling the people name node labels.
- 3 random graphs with the same random distribution of weights than **FDP1**. From our analysis (exponential random distribution with $\lambda = 4.6$, see section 3.1)
- 3 random graphs with uniform distribution of weights.

From each of these 10 random graphs we extracted the top 10 pairs of people names with highest rs and the top 20 pairs of people names with highest b .

A software application was developed to ask experts the relevance of pairs. The pairs were displayed to experts by random sampling from the mixed set of 300 people name pairs extracted from the semi-metric behavior of the real **PDP1** and 300 from the semi-metric behavior of random graphs. Given a pair of people names, experts were asked if the pair was relevant, not relevant, or they did not know the relevance. Figure 15 depicts the results.

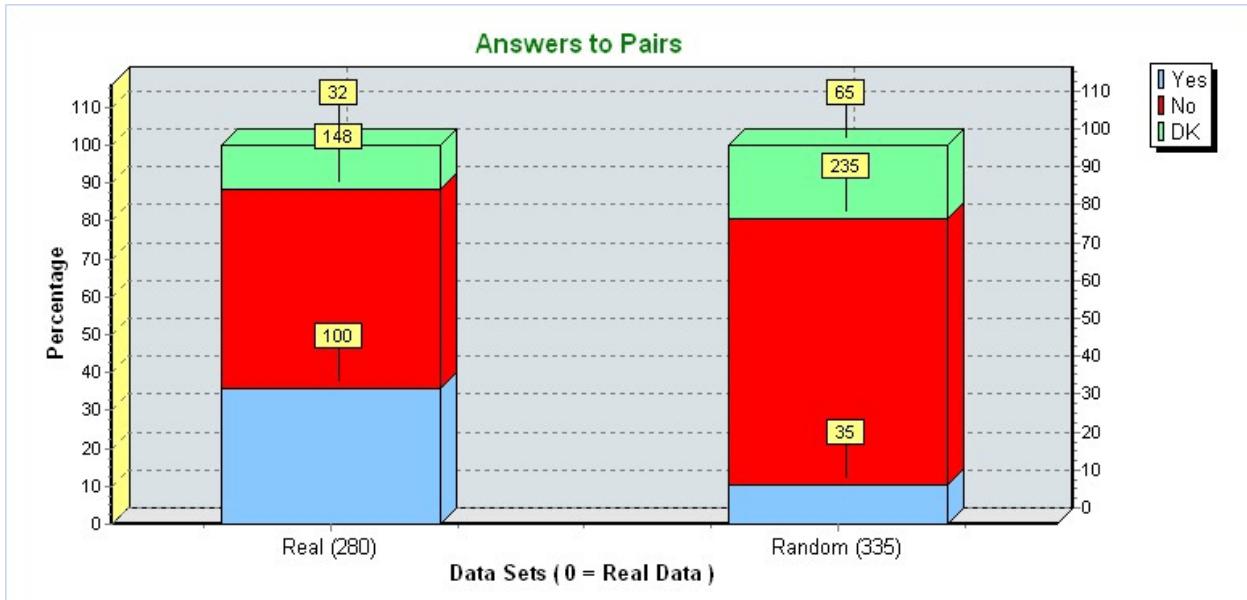

Figure 15: Comparison of expert responses to real semi-metric and random pairs.

Experts were asked about the relevance of 280 real pairs and 335 random ones. Of the real pairs, 36% were deemed relevant, 53% irrelevant, and 11% were unknown. Of the random pairs, 10% were deemed relevant, 70% irrelevant, and 20% the relevance was unknown.

We also calculated a measure of the uncertainty of expert responses. Experts were often posed the same pair more than once, and in some occasions responded differently. To measure this conflict among answers given to the same pairs of elements, we used the Shannon measure of uncertainty, which in this case becomes:

$$H(p_i, p_j) = - \left(m(\text{yes}) \cdot \log_2(m(\text{yes})) + m(\text{no}) \cdot \log_2(m(\text{no})) + m(\text{dk}) \cdot \log_2(m(\text{dk})) \right) \quad (11)$$

where $H(p_i, p_j)$ denotes the entropy for the answer to pair of names (p_i, p_j) , $m(\text{yes})$ is the probability of an expert answering “yes” to this pair, $m(\text{no})$ is the probability of an expert answering “no” to this pair, and $m(\text{dk})$ is the probability of an expert answering “don’t know” to this pair.

We computed the value of $H(p_i, p_j)$ for every pair that received more than one answer from the experts (86 out of 280 for the set of real pairs 107 out of 335 for the set of random pairs). The average entropy for these pairs was 0.2 for the real pairs and 0.33 for the random pairs.

The maximum value of H for three alternatives is 1.59. This value is achieved when the probability of answering yes, no, or don’t know are equal and 1/3. This would imply that in such a case the experts would be maximally uncertain about the answer – a state of complete lack of knowledge. Given the average entropies calculated, we can say that the expert entropy for the real pairs was 12.6% of maximum entropy, and for the random pairs it was 21%. These values are not error rates, but rather an indication of the level of uncertainty of experts in their answers. Experts were not completely certain of their answers, they were also far from complete uncertainty.

While the experts responded yes 36% of the time to real pairs and only 10% to random pairs, they still found that 53% of real pairs picked by the semi-metric methodology were irrelevant. We note that in other datasets this methodology has obtained much stronger positive expert response. For instance, in a separate experiment we obtained pairs of scientific journal names from the web logs of the Research Library at LANL. Experts responded yes 67% (no 9%) of the time to the real semi-metric pairs obtained from the analysis of the journal data set, and only yes 21% (no 52%) of the time to random journal pairs.

Several reasons can be found for such a relatively low level of yes answers in the **PDP1** data. First, in comparison to the journal data sets, the pool of experts was much smaller for **PDP1**. Also, as discussed in section 5, **PDP1** does not possess much or very strong semi-metric behavior. This means that there are not that many real latent associations to discover in this dataset to begin with. Finally, the semi-metric analysis used to discover latent behavior is not an ideal methodology to test by expert queries. Indeed, this analysis intends to discover novel associations that do not explicitly occur in expert data (namely documents in this case). Therefore, when we ask an expert, who compiled the documents, if an association that is not found in them makes sense, they are prone to respond “no” since they know of no document where the association is made.

The goal of this analysis is to discover “holes” in expert data in order to warn experts of potentially missing information. Therefore, another type of test discussed in the next subsection may be a better means to test the utility of the semi-metric methodology against this goal.

6.2 Random Deletions Test

This test was suggested by John Hogden; the idea is that if a given proximity graph captures “perfect” knowledge, then if we randomly delete some of its links, the semi-metric methodology should be good at recovering some of the deleted links – if it is a good methodology for discovering latent associations.

To produce a graph with “perfect knowledge”, we compute the transitive closure of a proximity graph. The transitive closure, a similarity relation (see section 2.1.7), captures all possible indirect associations in the data. The distance graph obtained from a similarity relation is fully metric – no semi-metric behavior is observed. We computed the transitive closures of **PDP1** and **PDP2**, which we name **PDP1^{TC}** and **PDP2^{TC}**, respectively.

Table 2: Results of full random deletions in **PDP1^{TC}**

p_del	%Total Pairs Deleted	stdv	%b	stdv	Corr	stdv
0	0	0	0	0	----	----

1	67.5	0	0	0	---	---

For each one of these similarity graphs we randomly deleted links with a certain probability. Specifically, we used $p_{\text{del}} = 0, 0.05, 0.1, \dots, 0.95, 1$. For every value of p_{del} we produced 100

graphs by deleting each link in the graph, independently, with this probability. That is, we produced 100 graphs by deleting, with 0.05 probability, links in PDP1^{TC} and PDP2^{TC} , 100 graphs for 0.1, etc.

Table 2 shows the results of these random deletions in PDP1^{TC} . For each level of probability of deletion, the second and third columns show the percentage of total positive links between pairs of elements on the graph that were actually deleted, and the standard deviation of this value (for 100 generated graphs) respectively. Notice that the percentage of links deleted accounts for only those links that had a positive proximity. Therefore, for these graphs, the percentage of actually deleted links is smaller than $p_{\text{del}} * 100$.

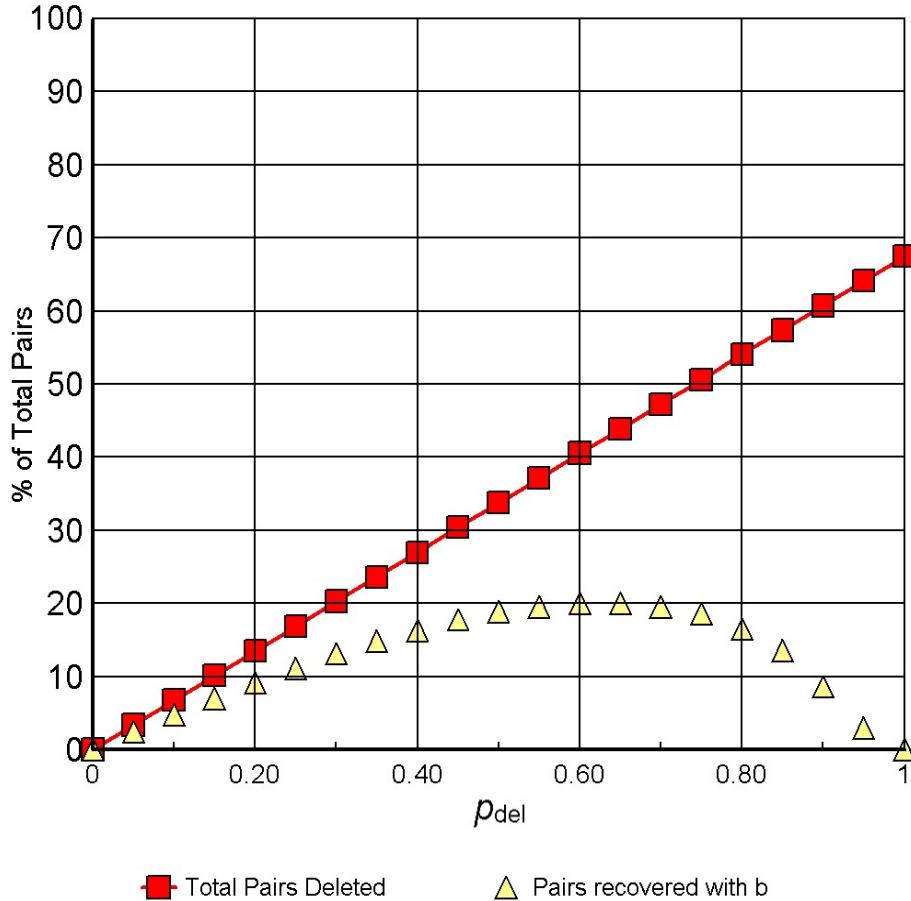

Figure 16: The horizontal axis represents the probability of deleting links (from 0 to 1). The vertical axis represents the percentage of total links deleted (red squares) and the percentage of total links recovered with the b parameter (yellow triangles) from the semi-metric analysis.

Given that $\mathbf{PDP1}^{\text{TC}}$ is a similarity graph, there is no semi-metric behavior for $p_{\text{del}} = 0$. Furthermore, since in this case we are completely deleting links, the s and rs semi-metric parameters are null for all pairs, and all values of p_{del} , as these parameters need a positive direct proximity value between a semi-metric pair to identify it as semi-metric. This is not the case of the b parameter which picks up pairs with no direct proximity values. The percentage of total pairs with $b > 1$, and its standard deviation, are shown in columns 4 and 5. Figure 16 depicts the values of actual deleted pairs and those recovered with b against different values of p_{del} .

We can see that for p_{del} up to 0.2, the semi-metric analysis is able to recover most deletions. As random deletions increase, the ability to recover deleted links decreases. In any case, as we can see in Figure 16, when $p_{\text{del}} = 0.6$, the semi-metric analysis is still capable of recovering half of all deleted links.

This shows that the semi-metric methodology is able to recover deleted links (or incomplete knowledge), but we still need to know how much the value of parameter b is an indication of the strength of the original deleted link. In other words, we want to know if a large value of b tends to imply a large deleted proximity. To measure the validity of this implication, we also computed the linear correlation coefficient between the value of b and the variation in deleted proximity, $\Delta PDP = pdp_{ij}(\text{initial}) - pdp_{ij}(\text{deleted})$ for deleted links – where $pdp_{ij} = \mathbf{PDP}(p_i, p_j)$, the value of proximity

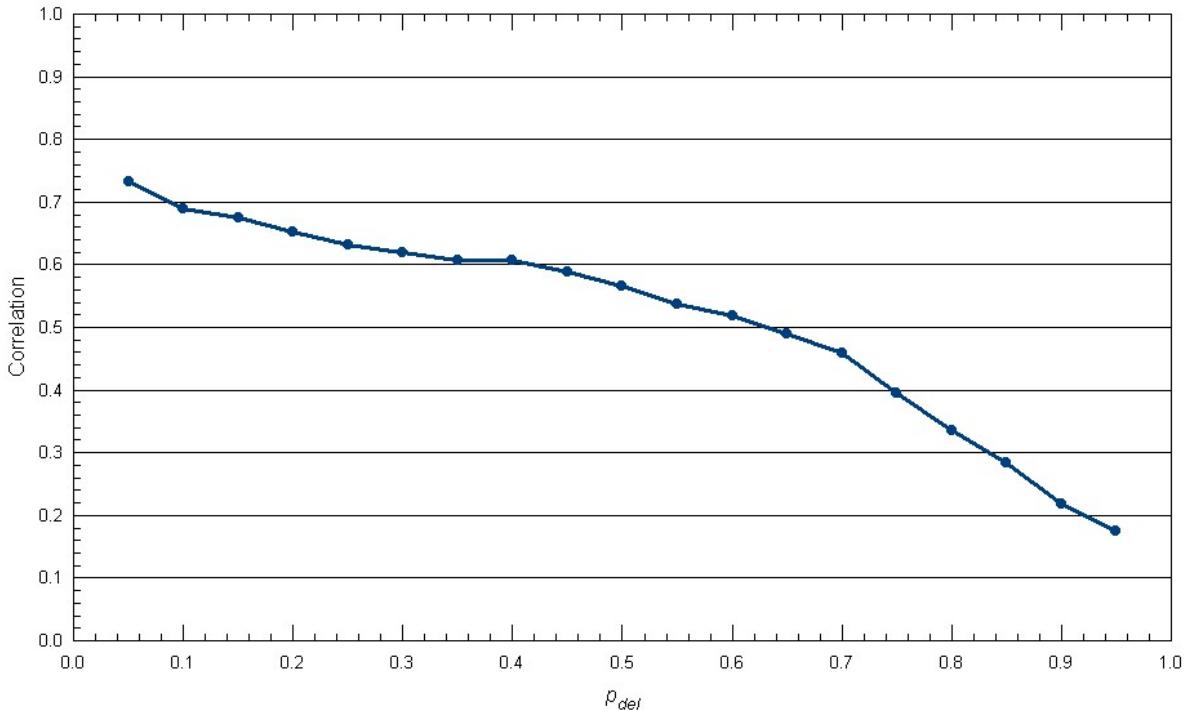

Figure 17: Plot of linear correlation between b and ΔPDP against p_{del}

for link (p_i, p_j) . In this case, pdp_{ij} (deleted) = 0. The value of this linear correlation and its standard deviation are shown in columns 6 and 7.

Figure 17 plots this linear correlation against the probability of deleting links, p_{del} . We can see that there is a distinct correlation for the initial values of random deletions. Until $p_{\text{del}} = 0.4$, this correlation is over 0.6. After this level of deletions the correlation decreases more rapidly. Thus, parameter b is a good measure of deleted links in **PDP1^{TC}** – it is able to recover deleted pairs, and its value is well correlated with the deleted value. This is a strong result for the validity of this methodology when used to discover missing evidence or knowledge.

We also conducted this random deletion analysis for the case of partial random deletion. That is, instead of completely deleting a link between a pair of elements, we reduce its value. Specifically, the process is exactly the same as above, but instead of pdp_{ij} (deleted) = 0, we have pdp_{ij} (deleted) = pdp_{ij} (initial) * u , where u is a uniform random variable in [0, 1]. Table 3 shows the results for this case. Since the deletions are partial, the s parameter detects partially deleted links – in addition to the b parameter which also detects deleted links.

Figure 18 depicts the percentage of total pairs deleted and those recovered with parameter s and b against the various levels of link deletions. The s parameter is very good at recovering most of the

partially deleted links; even at high levels of deletion a large percentage of partially deleted links are identified. For instance, at $p_{\text{del}} = 0.7$, more than 80% of deleted links are identified. The b parameter does not do as well in the partial deletion case, but that is to be expected since it was developed to capture completely missing data.

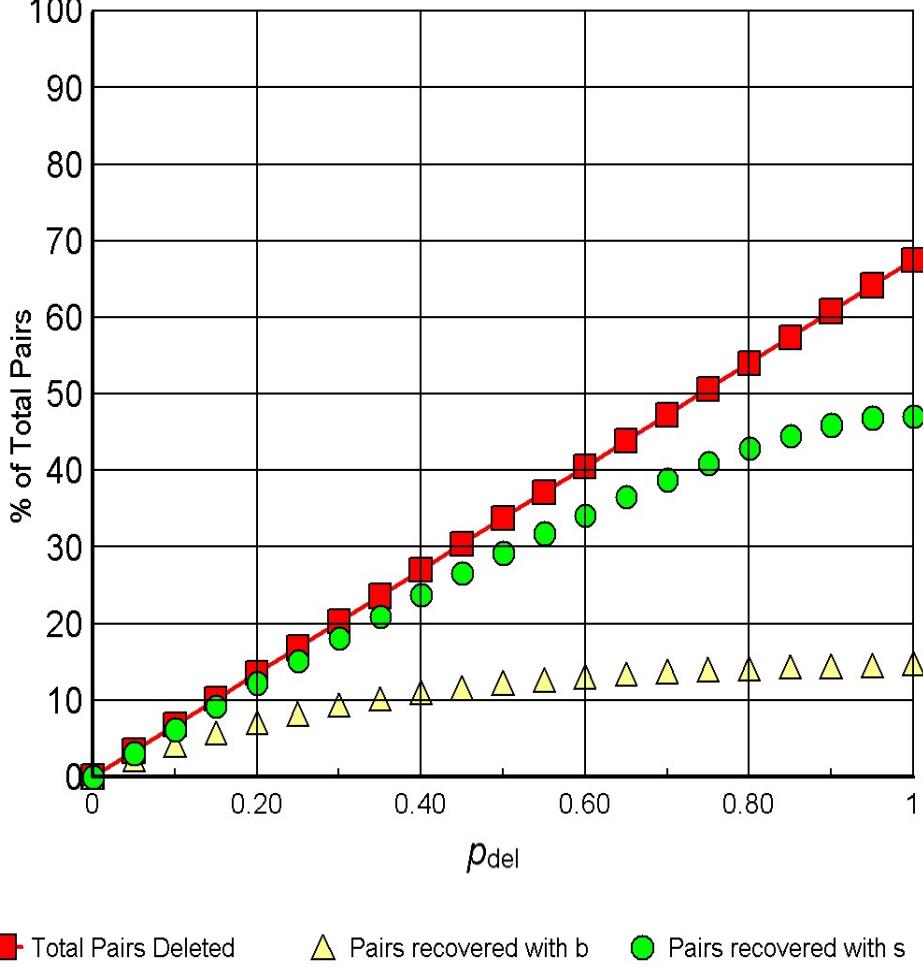

Figure 18: The horizontal axis represents the percentage of deleted positive links (from 0 to 100 %). The vertical axis represents the percentage of total links deleted (red squares), the percentage of total links recovered with the s parameter (green circles), and the percentage of total links recovered with the b parameter (yellow triangles) from the semi-metric analysis.

However, as it can be seen in table 3 and Figure 19, the value of s is not as correlated with ΔPDP as b is. In other words, even though the s parameter identifies most partially deleted links, it is not a very good measure of the amount of deleted information. The b parameter remains a good measure of the amount of information deleted for the smaller set of deleted links it identifies. This leads us

to posit that the s parameter (and the related rs) needs to be fine-tuned. In particular, one avenue for this development might be to tie it to the average distance of each node in a graph, as the b parameter is, but this is left for future work.

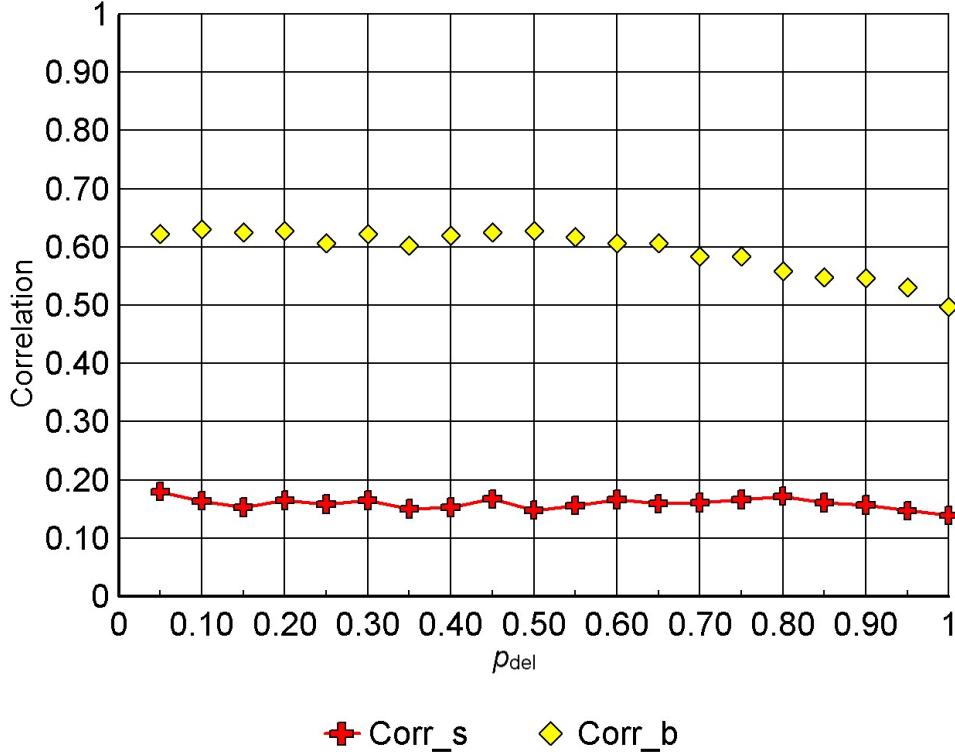

Figure 19: Correlation of s and b with ΔPDP for random partial deletion in $PDP1^{TC}$.

We computed the same random deletion scheme for $PDP2^{TC}$. As it can be seen in the appropriate tables and figures below, the semi-metric methodology was even slightly better for this case than $PDP1^{TC}$. The parameter b is able to recover slightly more completely deleted pairs and is slightly more correlated with the amount deleted. The same applies to parameter s in the partial random deletions case.

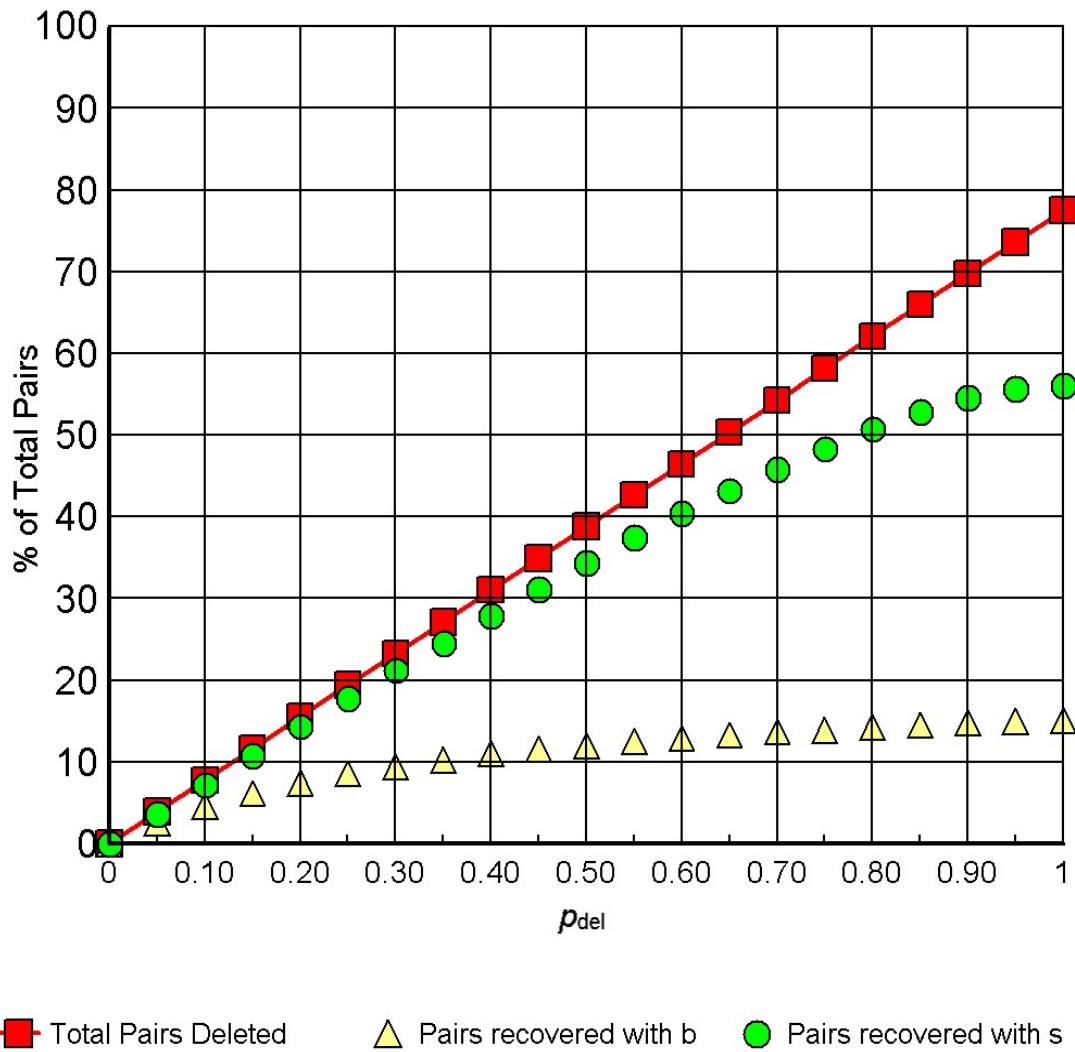

Figure 22: Percentage of deleted links, percentage of links recovered with parameter s and percentage of links recovered with parameter b for partial random deletion in PDP2^{TC}

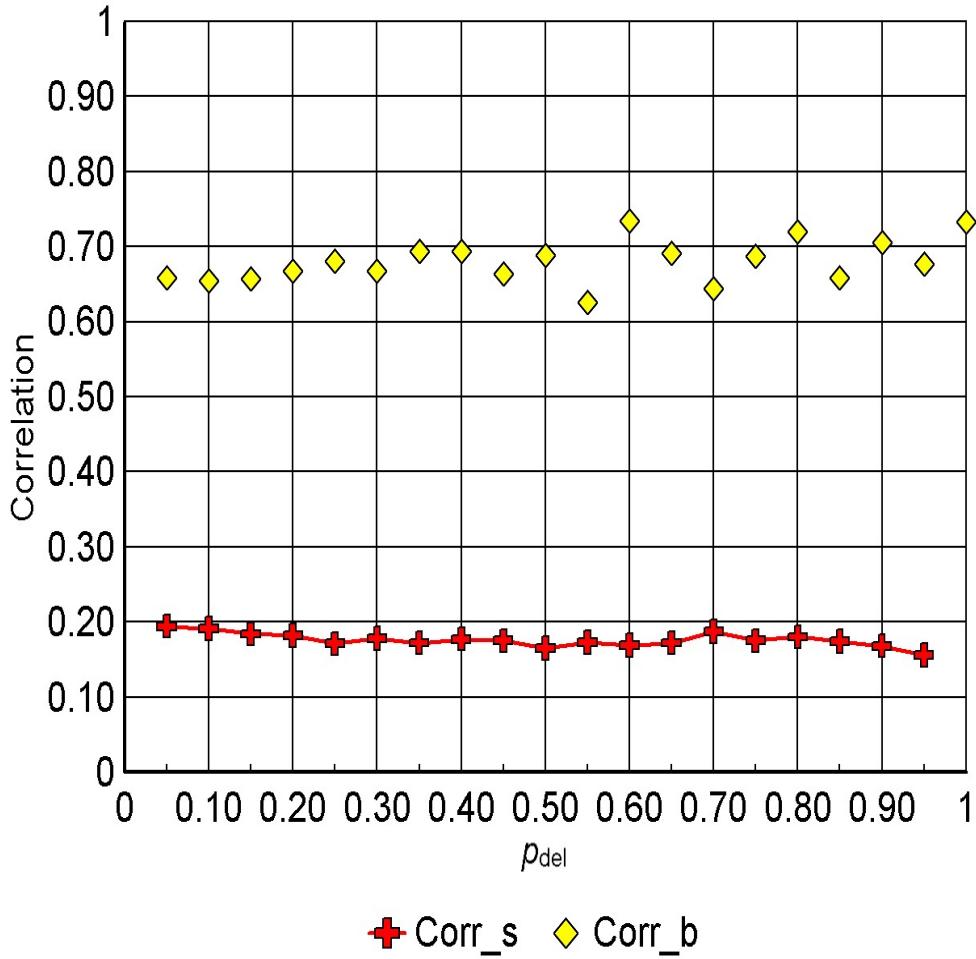

Figure 23: Correlation of parameters s and b with partially deleted proximity values in PDP2^{TC}

Finally, we note that we also computed this random deletion scheme for several random proximity graphs, and we observed that the semi-metric methodology is not able to recover deleted links well at all in such a case. This implies that this methodology is applicable to graphs that represent some real knowledge. We will leave the investigation of this conjecture for future work.

7 CONCLUSIONS AND FUTURE WORK

The proximity graphs we produced capture the direct associations between elements of a database field according to another field, e.g. co-occurrence of people names in documents. This provides a network representation of elements stored in a database, and allows us to discern what are the pairs of elements most associated with one another.

The semi-metric analysis adds to this the capacity to uncover latent associations between elements. That is, associations for which we do not possess direct evidence, but which are implied by the overall proximity network. The random deletion tests computed to test this methodology indicate that it is indeed successful at uncovering missing knowledge.

Several avenues of development remain for both proximity graphs and their semi-metric analysis, some of which are outlined below:

- Proximity graphs, mathematically are fuzzy graphs. As such, we can manipulate them with Fuzzy Set operations. For instance, we can calculate the unions and intersections of proximity graphs defined on the same set of elements. As an example, we can compute the intersection of **PDP2** with **PGP**, which would yield the proximity between people names according to co-occurrence in documents and participation in groups. A tool capable of manipulating these graphs in such a manner could be a useful analysis tool.
- The NETSTAT software could be developed as a database analysis tool, providing more effective visualization of graphs, as well as the ability to click on links to obtain the relevant evidence. For instance, clicking on a link between a pair of names in the **PDP2** graph would return the documents where the pair co-occurs.
- Improvement of the semi-metric parameters and better visualization techniques for this methodology.
- Integration of lattice visualization with proximity graphs.

0.3: Khalfan Khamis Mohamed, Ali Mohammad

A6. Pairs of people names with transitive closure of PDP2 ≥ 3

Percentage of Total: 1.8273 %

Number of Pairs: 921

1: Vladimir Putin, George Walker Bush
1: Tyron Santos, Yunus Moklis
1: Tohir Yuldashev, Abdul Akhad
1: Ruhal Ahmed, Shafiq Rasul
1: Redendo Dellosa, Yunus Moklis
1: Redendo Dellosa, Tyron Santos
1: Pio de Vera, Yunus Moklis
1: Pio de Vera, Tyron Santos
1: Pio de Vera, Redendo Dellosa
1: Nabil Nanakli Kosaibati, Nabil Sayadi
1: Mustafa Abdulkader Aabed al-Ansari, Sameer Mohammed Ahmed al-Hada
1: Muhammed Ali Mukhtar, Suleiman Asad
1: Muhammad Shawqi al-Islambuli, Tal'at Fu'ad Qasim
1: Muhammad Hussein Fadhlallah, Muhammad Ubaid
1: Movladi Uslugov, Wahhabi Achimez Gochiyayev
1: Mohamed Aouadi, Tarek Chaarabi
1: Mohamad Bahaih, Nabil Sayadi

1: Mohamad Bahaih, Nabil Nanakli Kosaibati
1: Mehdi Khammoun, Moktar Farid-Bouchoucha
1: Marvelo Egil, Yunus Moklis
1: Marvelo Egil, Tyron Santos
1: Marvelo Egil, Redendo Dellosa
1: Marvelo Egil, Pio de Vera
1: Latif Mansour, Saif Rahman
1: Khizir Alkhazurov, Uvais Akhmadov
1: Khalid Ibn Muhammad Al-Juhani, Muhammad Sa'id Ali Hasan
1: Khalid al-Shanqiti, Munir al-Mutasaddiq
1: Junior Jikiron, Ustadz Nur Mohammed Umog
1: Isma'il Shalabi, Tha'ir Mansour
1: Ibrahim Mamdouh Elleban, Mohamed Aouzar
1: Hamed Abderrahman Ahmed, Reswan Abdul Ulsalam
1: Hafiz Mohammed Saeed, Hassan Hattab
1: Habib Abd al-Rahman, Uvais Akhmadov
1: Habib Abd al-Rahman, Khizir Alkhazurov
1: Fouhad Sabour, Salim Boukhari
1: Fazlul Rehman Khalil, Sheikh Mir Hamza
1: Fayed Rashid Ahmed Hassan Al Qadi Banihammad, Mohand Alshehri
1: Fawaz Yahya Al-Rabeei, Sameer Mohammed Ahmed al-Hada
1: Fawaz Yahya Al-Rabeei, Mustafa Abdulkader Aabed al-Ansari
1: Farooq Kashmiri, Hassan Hattab
1: Farooq Kashmiri, Hafiz Mohammed Saeed
1: Faker Boussora, Muhammad Sa'id Ali Hasan
1: Faker Boussora, Khalid Ibn Muhammad Al-Juhani
1: Faizal Khan Gulam Sarwar, Mohd Agus Ahmad Selani.
1: Essoussi Laaroussi, Moktar Farid-Bouchoucha
1: Essoussi Laaroussi, Mehdi Khammoun
1: Bouraoui El-Ouaer, Mohamed Sliti
1: Asif Iqbal, Shafiq Rasul
1: Asif Iqbal, Ruhal Ahmed
1: Angelo Trinidad, Yunus Moklis
1: Angelo Trinidad, Tyron Santos
1: Angelo Trinidad, Redendo Dellosa
1: Angelo Trinidad, Pio de Vera
1: Angelo Trinidad, Marvelo Egil
1: Amar Chidek, Jean-Marc Granvisir
1: Al-Sa'id Ali Hasan Mukhlis, Gueddan Abdel Fatah
1: Ali Qaed Senyan al-Harthi, Mohammed Hamdi al-Ahdal
1: Ali al-Rashidi, Tal'at Fu'ad Qasim
1: Ali al-Rashidi, Muhammad Shawqi al-Islambuli
